Boundary-scan (JTAG or IEEE Std 1149.1) is an electronic serial interface that allows access to the special embedded logic on a many of today's ICs (chips).

~~Boundary Scan Tutorial~~

JTAG, boundary scan is a test technique that enables information about the state of a board to be gained when it is not possible to gain access to all the nodes that would be required if other means of test were used.

A boundary scan is a method to test the all interconnects on printed circuit boards (PCBs) using boundary scan cells instead of physical probes. It is a standard widely adopted by electronic companies. Prototype debugging and product design can also benefit from boundary scans.

~~Constraints on the Use of Boundary Scan for Fault Injection~~

Board security enhancement using new locking SIB-based architectures Abstract: Circuit boards are especially vulnerable to security attacks. Many routes and pins can be probed directly. Other pins may be controlled and observed through the JTAG boundary scan port.

Shorting jumper shunts are frequently used to configure a unit under test (UUT) a particular way for boundary-scan testing–perhaps a compliance enable signal must be met or FPGA configuration needs to be inhibited.

~~Boundary Scan Tutorial~~

Boundary scan is a method for testing interconnects (wire lines) on printed circuit boards or sub-blocks inside an integrated circuit. Boundary scan is also widely used as a debugging method to watch integrated circuit pin states, measure voltage, or analyze sub-blocks inside an integrated circuit.

In fact, the boundary-scan path is independent of the function of the device. The value of the scan path is at the board level as shown in Figure 11. The figure shows a board containing four boundary-scan devices. Notice that there is an edge- connector input called TDI connected to the TDI of the first device.

In general, execution of JTAG private instructions is deemed as a good example of one attack surface. Sometimes (but not always), security-related data/functions are hidden behind undocumented instruction encodings that are not revealed by the Boundary Scan Description Language (BSDL) file of the chip.
