Thinking that digital implementations are always better, our clever engineer wants

to design a digital AM receiver. The receiver would bandpass the received signal, pass the result through an A/D converter, perform all the demodulation with digital signal processing systems, and end with a D/A converter to produce the analog message signal.

A discrete-time signal $x(n]$ is defined as (a) Determine its values and sketch the signal $x(n]$. (b) Sketch the signals that result if we: 1. First fold $x(n]$ and then delay the resulting signal by four samples. 2. First delay $x(n]$ by four samples and then fold the resulting signal. (c) Sketch the signal $x(-n + 4]$.

We know how to acquire analog signals for digital processing (pre-filtering, sampling, and A/D conversion) and to compute spectra of discrete-time signals (using the FFT algorithm), let's put these various components together to learn how the spectrogram shown Fig. 5.10.1 below, which is used to
