interpolation, both operated by an MWNI engine, under the above mentioned most challenging scenarios: spatial aliasing of incomplete curving diffractions, and large up-sampling of regularly missing data (deliberately decimated in this experiment by 3 times).

Five Dimensional Interpolation New Directions

Five-dimensional (5D) interpolation has been in the industry for almost ten years now, and has become widely accepted and used. There are now a variety of implementations, with different algorithms and flavors. Our understanding of interpolation has grown greatly in the last decade because of its use in increasingly challenging scenarios.

for a given location on the square the bits encode only the walls in the *positive* direction of each axis. For example, for a 2d maze the bits encode the presence of a wall wall in the "down" and "right" directions, respectively (but the ability to move "up" or "left" is determined by the presence of walls in the corresponding neighboring squares).

(5) for 2-dimensional interpolation. There a new set of 5×7 and 7×5 matrices are created from the input set of 3×4 and 4×3 matrices respectively. The central point of these new sets of matrices are two new predicted values for the target pixel. These two intensity values, with the four values from one-

Linear interpolation allows us to improve an estimate based on a set of x- and y-values. What if you are working with x-, y- and z-values, where x and y are independent variables and z is dependent on both? In that case, you can use bilinear interpolation in Excel. It works similarly to linear interpolation... Read more about Bilinear Interpolation in Excel

Five-dimensional (5-D) interpolation is a wide umbrella covering methods that simultaneously interpolate all space dimensions – and although it is not possible to get the same quality from interpolated traces as the traces recorded in the field, 5-D interpolation has proven to be quite successful.

The f-k interpolation method is based on creating a mask function from the low frequency portion of the data and applying it to interpolate the high frequencies. The mask function is created by properly zero-padding and zero-interlacing the original data. The principle of the f-k interpolation remains the same for 3D and higher dimensional

images. Here, we take the seismic interpolation as an image super-resolution problem and will adopt a similar RDNet as the study of Zhang et al. (2018) for seismic interpolation. Figure 1 shows the architecture of the RDNet, in which the input is seismic data with missing traces, and output is the data after interpolation.
