Being responsive to lateral variations in rock properties, gravity and magnetic methods are best suited for detecting steep discontinuities such as faults. Seismic methods, by contrast, are best for detecting vertical rock variations and low-angle discontinuities such as layer boundaries.

Magnetic methods share fundamental similarities with gravity methods. In magnetic surveys, as in gravity surveys, the total strength of the field is measured at points on or above the surface, except that the measurements are sensitive to rock magnetization rather than rock density. Igneous rocks typically have much higher intensities of magnetization than sedimentary rocks; so, magnetic data are useful for assessing sediment thickness over basement.

This is the crux of the magnetohydrodynamic theory of the geomagnetic field (see also Earth: Sources of the steady magnetic field). Gravity methods. The gravity field of the Earth can be measured by timing the free fall of an object in a vacuum, by measuring the period of a pendulum, or in various other ways.

- Geophysical exploration techniques that employ both gravity and magnetics are passive. By this, we simply mean that when using these two methods we measure a naturally occurring field of the earth: either the earth's gravitational or magnetic fields. Collectively, the gravity and magnetics methods are often referred to as
